Citation style for this article:

Emerging drug resistance in Salmonella Typhi and S. Paratyphi is a substantial public health concern. We report what appears to be the first case and isolation of multidrug resistant S. Paratyphi A carrying CTX-M-15-type extended-spectrum beta-lactamase from a Japanese traveller returning from India.

Here, we report the isolation of multidrug resistant S. Paratyphi A producing CTX-M-15-type extended-spectrum beta-lactamase (ESBL) from a traveller returning from India. To our knowledge, this is the first report of S. Paratyphi A with CTX-M-15-type ESBL isolated from a human. Enteric fever, including typhoid fever caused by S. enterica serotype Typhi (S. Typhi) and paratyphoid fever caused by S. enterica serotype Paratyphi A (S. Paratyphi A), is one of the most important febrile illnesses in tropical and subtropical countries, with high rates of morbidity and mortality [1]. In industrialised countries, enteric fever is a common cause of fever in returned travellers [2]. The emergence of drug-resistance in S. Typhi and S. Paratyphi A is an emerging public health problem. Owing to the recent increase of fluoroquinolone resistance, third-generation cephalosporins, such as ceftriaxone or cefotaxime, have become the primary drugs for treatment of enteric fever [3].

Case report

In July 2013, a Japanese woman in her mid-20s was admitted to a hospital in Manali, India for fever over 38.5 ºC, diarrhoea, and anorexia, where she was diagnosed with typhoid fever based on clinical symptoms and a non-specifed rapid serological test. She had been in India for five weeks prior to the admission. Before her visit to India, she had been on a seven-week trip to China, Myanmar, Thailand, and Nepal. She was treated with parenteral cefalosporin for three days.

No further details on the treatment regimen in India were available. The patient returned to Japan on day 4 of illness owing to sustained fever, diarrhoea, and anorexia. During her travel from India to Japan (days 5–7), the patient took oral combined ofloxacin-cefixime. On day 7, she was admitted to our hospital with diarrhoea and anorexia but without fever. On examination, deep palpation of the lower abdominal area caused mild discomfort, otherwise, physical examination was normal. She did not have any underlying illness, and was not on any regular medication. Eight months prior to the admission at the hospital in India she had been vaccinated against Salmonella Typhi (Vi polysaccharide).

Laboratory analyses

On admission, stool and blood samples were taken for culture. Antimicrobial susceptibility test was performed by broth microdilution in accordance with the Clinical and Laboratory Standards Institutes [4]. The patient’s stool was screened on admission for meticillin-resistant Staphylococcus aureus, vancomycin-resistant Enterococci, and Gram-negative rods resistant to one or multiple agents in the extended-spectrum cephalosporin class and/or that demonstrated elevated minimum inhibitory concentrations (MICs) (>1 mg/L) to imipenem and/or meropenem. Screening culture of stool was positive only for drug-sensitive Escherichia coli and Enterobacteriaceae spp.

Results from blood cultures were positive for S. Paratyphi A two days after admission and S. Paratyphi A was found to be resistant to cefotaxime (MIC = 64 mg/L) and ceftazidime (MIC > 16 mg/L). Addition of clavulanic acid to each cephalosporin lowered the MIC to 0.25 mg/L and 1 mg/L, respectively. This isolate was also resistant to nalidixic acid, and categorised as...
The MIC breakpoint for azithromycin is not provided by the Clinical and Laboratory Standards Institute. We thus refer to the breakpoints table by the European Committee on Antimicrobial Susceptibility Testing, which mentions that azithromycin has been used in the treatment of infections with Salmonella Typhi (MIC ≤16 mg/L for wild type isolates) [5].

Of particular concern are reports of increasing isolation rates of S. Paratyphi A from India and other parts of Asia [14], which might be attributed to use of protective vaccines (Vi polysaccharide and live oral Ty21a) effective against S. Typhi, but not S. Paratyphi A [14].

The number of reports on ESBL in S. Typhi and S. Paratyphi A is still limited, and thus, extended-spectrum cephalosporins would still be a reasonable empiric treatment for a suspected case of enteric fever in the current situation. The patient improved on day 8 before antibiotics were changed. The oral treatment by a fluoroquinolone (ofloxacin) prior to the admission might have contributed to her clinical improvement. Other possible explanations include clinical recovery due to natural history of S. Paratyphi A, or infection of two different antimicrobial patterns of S. Paratyphi A, i.e. ESBL-S. Paratyphi A and non-ESBL-S. Paratyphi A, with non-ESBL mainly contributing to clinical symptoms.

Potential increase in the plasmid-mediated spread of ESBL in S. Paratyphi A in the future would pose a threat to public health. Judicious use of antibiotics to avoid unnecessary selective pressure on intestinal bacterial flora, and careful microbiological analysis of patients with typhoid fever, especially those returning from the Middle East or south Asia are approaches critical for prevention of the potential spread of multidrug-resistant S. Paratyphi A.
